endodontic treatment saves the tooth from extraction but only adequate restoration will reinstate it as a long term functioning member of the mouth the restoration of a tooth by root canal treatment is of limited value unless the crown of tooth is satisfactorily restored the manner in which a root canal filled tooth is restored is therefore considerable importance the restoration of endodontically treated tooth is complicated by the fact that much or all of the coronal tooth structure which normally would be used in the retention of the restoration has been destroyed by caries previous restorations trauma and the endodontic access preparation itself the endodontically treated tooth is a unique subset of teeth requiring restoration because of several factors such as dehydrated dentin decreased decreased structural integrity and impaired neurosensory feed back

mechanism when compared to a vital tooth however the treatment goal must be based upon a multitude of factors specific for each patient so that the strategic architectural aspects that have greatest impact on the ultimate strength of the pulpless tooth can be restored reinforced

endodontic treatment is largely performed on teeth significantly affected by caries multiple repeat restorations and or fracture already structurally weakened such teeth are often further weakened by the endodontic procedures designed to provide optimal access and by the restorative procedures necessary to rebuild the tooth root canal treatment weakens tooth structure and predisposes teeth to fracture root filled teeth are more susceptible to fracture than teeth with intact pulps because of loss of tooth structure due to caries trauma and root canal preparation use of intracanal medicament and few irrigants also contributes to decrease in fracture resistance of tooth in addition lateral compaction creates stresses in the root during obturation which could lead to subsequent fracture

restoration of an endodontically treated tooth because of the significant loss of tooth structure often requires additional support from the root canal by means of a post and core restoration however post may generate stresses which lead to vertical root fracture and loss of the tooth since post design material used and the post space preparation has a significant influence on vertical fracture prevalence broad investigation is in progress to find out the optimum procedure esthetic functional and structural rehabilitation of a

pulpless tooth are critically important to ensure a successful restorative outcome in cases where most of the coronal portion is lost a common method to restore such teeth is the use of a post and core onto which a full crown is cemented the post functions primarily to aid the retention of the restoration and to protect the tooth by dissipating or distributing forces along the tooth on the contrary the tooth is weakened if dentin is sacrificed to place a large diameter dowel the main purpose of this study was to evaluate the ability of different types of posts to reinforce endodontically treated teeth

when faced with the challenge of restoring an endodontically treated tooth the dentist must decide first whether the post is required and second the type of restoration that is indicated earlier a post was thought to strengthen the root of an endodontically treated tooth but it is widely held today that the primary purpose of post placement is to retain the

core buildup material or to reinforce the remaining coronal tooth structure it is difficult to discuss the longevity of teeth restored by a post because there are many variables to control the long term clinical success of an endodontically treated tooth is dependent on many factors the successful treatment of a badly broken down tooth with pulpal disease depends not only on good endodontic therapy but also on good prosthetic reconstruction of the tooth after endodontic therapy is completed the decision to place a post is based on several parameters these include the position of the tooth in the arch occlusion function of the restored tooth amount of remaining tooth structure and canal configuration

this book is a comprehensive guide to apical periodontitis in root filled teeth that covers not only all aspects of diagnosis and management but also epidemiology etiology consequences clinical decision making and prognosis there is a particular focus on the available surgical and nonsurgical methods of retreatment designed to restore healthy periapical conditions alternatives to retreatment are also explored including a conservative approach involving monitoring of the diseased tooth without intervention and the option of extraction and replacement with an implant or a fixed prosthesis the goal of root canal treatment is to save the natural tooth even when tissue breakdown has resulted in pathological conditions of the pulp and periradicular tissue however population studies reveal that complete healing is often absent in root filled teeth and apical periodontitis is frequently observed in conjunction with root fillings of poor technical quality under these circumstances questions arise as to how the apical periodontitis is impacting on the patient and how the condition should be tackled readers will find this well illustrated book to be of great value in directing clinical practice

this resource emphasizes the clinical aspects of endodontics an extensive collection of

before and after patient cases are illustrated with a generous number of radiographs many of which span over 25 years posttreatment offering relevant information in a convenient size this 6th edition reflects the major changes in instruments techniques in canal preparation and the advances in canal filling that have occurred in the field discussions of drug therapy include coverage of non steroidal antiinflammatory drugs nsoids retreatment and restoration of the endodontically treated tooth are addressed non surgical alternatives to routine endodontic treatment are included the simple concise language makes difficult topics easy to understand
